MyRs Cheat Sheet

Quick Reference — Draft v1.0 (October 28, 2025)

This template sets up a compact, two-column A4 layout. Listings are configured for small print and good readability.

1 Cargo Quick Commands

- `cargo new myproj` – Create new binary project
- `cargo new -lib mylib` – Create new library crate
- `cargo new -bin myproj` – Create new binary project
- `cargo add <crate>` – Add dependency
- `cargo check` – Check code without building
- `cargo clippy` – Lint code
- `cargo doc -open` – Generate and open docs
- `cargo run` – Build and run
- `cargo run -quiet` – Quiet run
- `cargo build -release` – Optimized build
- `cargo build -quiet` – Quiet build
- `cargo clean` – Remove build artifacts
- `cargo bench` – Run benchmarks
- `cargo test` – Run tests
- `cargo fmt` – Format code

2 Hello, world! (Rust)

Create and compile with bash:

```
# Create file
touch main.rs
```

Rust code:

```
fn main() {
    println!("Hello, world!");
}

# Compile with rustc
rustc main.rs

# Run the binary
./main
```

2.1 File Naming Convention

- ✓ `hello_world.rs` – Correct: snake_case
- ✗ `helloworld.rs` – Wrong: no separator

3 Variables and Types

```
fn main() {

    // Scalar types:

    let decimal: i32 = 98_222;      // Integer
    let hex: i32 = 0xff;            // Hexadecimal
    let octal: i32 = 0o77;          // Octal
    let binary: i32 = 0b1111_0000;  // Binary
    let byte: u8 = b'A';            // Byte (u8)
    let character: char = 'R';      // Character
    %let hugging_face: char = ''; // Unicode character

    //Compound types:

    let tuple: (i32, f64, u8) = (500, 6.4, 1);
    let (a, b, c) = tuple;
    let array: [i32; 4] = [1, 2, 3, 4];
    let first = array[0];

    // Constants:
    const MAX_POINTS: u32 = 100_000;

}
```

3.1 Mutability

```
fn main() {
    let x = 5;     // immutable variable by default
    println!("Initial x: {}", x); // 5
    // x = x + 1;  // error: cannot assign twice to immutable variable

    let mut x = 5; // mutable variable
    println!("Initial x: {}", x); // 5
    x = x + 1;     // modify x
    println!("Modified x: {}", x); // 6
}
```

3.2 Shadowing

```
fn main() {
    let x = 5;
    let x = x + 1; // shadows previous x
    {
        let x = x * 2; // shadows again in inner scope
        println!("Inner x: {}", x); // 12
    }
    println!("Outer x: {}", x); // 6
}
```

3.2.1 Shadowing vs Mutability

```
fn main() {
    // using mutability
    let mut x = 5;
    x = x + 1; // modify x
    println!("Mutable x: {}", x); // 6
    // using shadowing
    let x = 5;
    let x = x + 1; // shadow previous x
    println!("Shadowed x: {}", x); // 6
}
```

4 Macros

4.1 Declarative Macros

```
macro_rules! greet {
    ($name:expr) => {
        println!("Hello, {}!", $name);
    };
}
fn main() {
    greet!("Alice"); // Hello, Alice!
    greet!("Bob");   // Hello, Bob!
}
```

4.2 Procedural Macros

Procedural macros work on the abstract syntax tree (AST) of Rust code.

Types:

- **Derive macros:** `#[derive(MyTrait)]`
- **Attribute macros:** `#[my_attribute]`
- **Function-like macros:** `my_macro!(input)`

Example: Custom Derive Macro

```
// In Cargo.toml:
// [lib]
// proc-macro = true

use proc_macro::TokenStream;
use quote::quote;
use syn::{parse_macro_input, DeriveInput};

#[proc_macro_derive(HelloMacro)]
pub fn hello_macro_derive(input: TokenStream) -> TokenStream {
    let ast = parse_macro_input!(input as DeriveInput);
    let name = &ast.ident;

    let gen = quote! {
        impl HelloMacro for #name {
            fn hello_macro() {
                println!("Hello from {}!", stringify!(#name));
            }
        }
    };
    gen.into()
}
```

Usage:

```
trait HelloMacro {
    fn hello_macro();
}

#[derive(HelloMacro)]
struct Pancakes;

fn main() {
    Pancakes::hello_macro(); // Hello from Pancakes!
}
```

5 Control Flow

```
fn main() {
    let number = 6;
    if number % 2 == 0 {
        println!("{} is even", number);
    } else {
        println!("{} is odd", number);
    }
}
```

5.1 Combining Conditions

```
fn main() {
    let number = 6;
    if number > 0 && number % 2 == 0 {
        println!("{} is a positive even number", number);
    } else if number > 0 && number % 2 != 0 {
        println!("{} is a positive odd number", number);
    } else {
        println!("{} is not positive", number);
    }
}
```

OR || operator

```
fn main() {
    let number = 6;
    if number > 0 || number % 2 == 0 {
        println!("{} is a positive even number", number);
    } else if number > 0 || number % 2 != 0 {
        println!("{} is a positive odd number", number);
    } else {
        println!("{} is not positive", number);
    }
}
```

5.2 Basic Loop

```
fn main() {
    let mut count = 0;
    loop {
        count += 1;
        if count == 5 {
            break;
        }
        println!("Count: {}", count);
    }
}
```

5.2.1 Loop Labels

```
fn main() {
    let mut count = 0;
    'outer: loop {
        count += 1;
```

```
        let mut inner_count = 0;
        loop {
            inner_count += 1;
            if inner_count == 3 {
                break 'outer; // breaks the outer loop
            }
            println!("Inner Count: {}", inner_count);
        }
        println!("Count: {}", count);
    }
}
```

6 For and While

```
fn main() {
    let numbers = [10, 20, 30, 40, 50];
    for n in numbers.iter() {
        println!("Number: {}", n);
    }
}
```

```
fn main() {
    let mut count = 0;
    while count < 5 {
        println!("Count: {}", count);
        count += 1;
    }
}
```

6.1 Range in For Loop

```
fn main() {
    for i in 1..=5 { // inclusive range
        println!("i: {}", i);
    }
}
```

6.2 Break and Continue

```
fn main() {
    for i in 1..10 {
        if i % 2 == 0 {
            continue; // skip even numbers
        }
        if i > 7 {
            break; // exit loop if i > 7
        }
        println!("Odd i: {}", i);
    }
}
```

7 Pattern Matching

```
fn main() {
    let number = 3;
    match number {
        1 => println!("One"),
        2 => println!("Two"),
        3 | 4 | 5 => println!("Three, Four, or Five"),
        _ => println!("Something else"),
    }
}
```

Or | operator

```
fn main() {
    let x = 2;
    match x {
        1 | 3 | 5 => println!("Odd"),
        2 | 4 => println!("Even"),
        _ => println!("Something else"),
    }
}
```

Matching Ranges

```
fn main() {
    let x = 5;
    match x {
        1..=5 => println!("In range 1 to 5"),
        _ => println!("Out of range"),
    }
}
```

Ignoring Values with __

```
fn main() {
    let point = (3, 5);
    match point {
        (x, _) => println!("x is {}, y is ignored", x),
    }
}
```

8 Functions

```
    fn greet(name: &str) {
        println!("Hello, {}!", name);
    }
    fn main() {
        greet("Alice");
        greet("Bob");
    }
```

8.1 Functions with Return Values

```
    fn add(a: i32, b: i32) -> i32 {
        a + b
    }
    fn main() {
        let sum = add(5, 10);
        println!("Sum: {}", sum);
    }
```

9 Statements and Expressions

```
fn main() {
    let x = 5; // statement
    let y = {
        let z = 10; // statement
        z + 5      // expression
    }; // expression

    println!("x: {}, y: {}", x, y);
}
```

If as an Expression

```
fn main() {
    let condition = true;
    let number = if condition { 5 } else { 10 }; // if expression
    println!("The number is: {}", number);
}
```

match as an Expression

```
fn main() {
    let number = 3;
    let result = match number {
        1 => "One",
        2 => "Two",
        3 => "Three",
        _ => "Something else",
    }; // match expression
    println!("The result is: {}", result);
}
```

10 Ownership and Borrowing

```
fn main() {
    let s1 = String::from("hello"); // s1 owns the string
    let s2 = s1;                    // ownership moved to s2
    // println!("{}", s1);          // error: s1 is no longer valid

    let s3 = String::from("world");
    let s4 = &s3;                   // borrow s3
    println!("s3: {}, s4: {}", s3, s4); // both valid
}// s3 and s4 go out of scope here
```

10.1 Stack and Heap

- **Stack:** Fast, fixed-size data. FiFo structure.
- **Heap:** Dynamic-size data. Slower access due to indirection.

```
fn main() {
    let x = 5;              // stored on stack
    let s1 = String::from("hello"); // stored on heap
    let s2 = s1;           // ownership moved to s2
    // println!("{}", s1);  // error: s1 is no longer valid
    println!("x: {}, s2: {}", x, s2);
} // x and s2 go out of scope here and memory is freed
```

10.2 String Type

String Literals: immutable, fixed-size, stored on stack, example:

```
let s: &str = "Hello, world!"; // string slice (immutable)
```

String Type: mutable, growable, stored on heap, example:

```
let mut s = String::from("Hello"); // String type (mutable)
```

10.3 Ownership and Scope

```
fn main() {
    {
        let s = String::from("hello"); // s is valid here
        println!("{}", s);
    } // s goes out of scope and memory is freed here
}
```

10.4 Move

moving with integers:

```
fn main() {
    let x = 5;
    let y = x; // x is moved to y - Copy trait for integers
    // println!("{}", x); // error: x is no longer valid
    println!("{}", y);
}
```

moving with String:

```
fn main() {
    let s1 = String::from("hello");
    let s2 = s1; // s1 is moved to s2 - ownership transferred
    // println!("{}", s1); // error: s1 is no longer valid
    println!("{}", s2);
}
```

Notes: When you create a String, the actual string struct itself is stored on the stack, but the contents (the characters) are stored on the heap. When you move a String, you are transferring ownership of the heap data to the new variable. **Shallow Copy** means copying only the pointer to the data, not the data itself. In Rust, moving a String is like a shallow copy because the ownership of the heap data is transferred to the new variable, and the original variable can no longer access it.

11 Result and Error Handling

```
use std::fs::File;
use std::io::{self, Read};

fn read_path(path: &str) -> io::Result<String> {
    let mut s = String::new();
    File::open(path)?.read_to_string(&mut s)?;
    Ok(s)
}
```

12 Vector and Match

```
fn main() {
    let numbers = vec![1, 2, 3, 4, 5];
    for n in &numbers { println!("{n}"); }

    match numbers.get(10) {
        Some(x) => println!("found: {x}"),
        None => println!("none"),
    }
}
```

13 Trait and Impl

```
trait Area { fn area(&self) -> f64; }

struct Circle { r: f64 }

impl Area for Circle {
    fn area(&self) -> f64 { std::f64::consts::PI * self.r * self.r }
}

fn main() {
    let c = Circle { r: 2.0 };
    println!("area = {}", c.area());
}
```

14 Creating Custom Error Types

```
use std::fmt;

#[derive(Debug)]
enum MyError {
  NotFound,
  InvalidInput,
  ConnectionError,
}

impl fmt::Display for MyError {
  fn fmt(&self, f: &mut fmt::Firmatter) -> fmt::Result {
    match self {
      MyError::NotFound => write!(f, "Resource not found"),
      MyError::InvalidInput => write!(f, "Invalid input provided"),
      MyError::ConnectionError => write!(f, "Connection error occurred"),
    }
  }
}
```

15 Logging

The ‘log‘ crate provides a lightweight logging facade. To use it:

```
use log::{info, warn, error, debug};

fn main() {
    env_logger::init();
    info!("Starting application");^
    warn!("Low disk space");
    error!("Failed to connect to database");
    debug!("Debugging information");
}
```

The slog crate is another popular logging library that provides more features and flexibility.

```
use slog::{Drain, Logger, o, info};
use slog_async;
use slog_term;

fn main() {
    let decorator = slog_term::TermDecorator::new().build();
    let drain = slog_term::CompactFormat::new(decorator).build().fuse();
    let drain = slog_async::Async::new(drain).build().fuse();
    let log = Logger::root(drain, o!());

    info!(log, "Application started");
}
```

16 Quick Notes

- **Docs/Help:** `rustup doc` and `cargo -help`.
- **Format:** `rustfmt` (automatic). **Lint:** `clippy`.
- **Toolchains:** `rustup toolchain list`, `rustup override`.
- **Tests:** `#[test]` and `cargo test -q`.
- **Performance:** build with `-release`, `cargo bench` (nightly).

17 Generics

17.1 Generic functions

```
fn first_element<T>(list: &[T]) -> Option<&T> {
    if list.is_empty() {
        None
    } else {
        Some(&list[0])
    }
}

fn main() {
    let numbers = vec![1, 2, 3];
    let words = vec!["hello", "world"];

    if let Some(first_num) = first_element(&numbers) {
        println!("First number: {}", first_num);
    }

    if let Some(first_word) = first_element(&words) {
        println!("First word: {}", first_word);
    }
}
```

17.2 Generic structs

```
struct Point<T> {
    x: T,
    y: T,
    z: i32,
}

impl<T> Point<T> {
    fn new(x: T, y: T, z: i32) -> Self {
        Point { x, y, z }
    }
}

fn main() {
    let int_point = Point::new(1, 2, 3);
    let float_point = Point::new(1.0, 2.0, 3.0);

    println!("Integer Point: ({}, {}, {})", int_point.x, int_point.y, int_point.z);
    println!("Float Point: ({}, {}, {})", float_point.x, float_point.y, float_point.z);
}
```

17.3 Generic Enums

```
enum Option<T> {
    Some(T),
    None,
}

fn main() {
    let some_number = Option::Some(5);
    let no_number: Option<i32> = Option::None;

    match some_number {
        Option::Some(value) => println!("Got a number: {}", value),
        Option::None => println!("No number"),
    }

    match no_number {
        Option::Some(value) => println!("Got a number: {}", value),
        Option::None => println!("No number"),
    }
}
```

17.4 Notes:

- Using generics doesnt slow down your code. The compiler generates optimized versions for each type used.
- Monomorphization is the process of generating specific implementations for each type used with generics.
- Monomorphization happens at compile time, so there is no runtime overhead.

18 Traits

- Traits define shared behavior across types.
- A trait is like a contract that types can implement.
- Traits enable polymorphism and code reuse.

18.1 Defining and Implementing Traits

```
pub trait Summary {
    fn summarize(&self) -> String {
        String::from("(Read more...)") // default implementation
    }
}

struct NewsArticle {
    headline: String,
    location: String,
    content: String,
}

impl Summary for NewsArticle {
    fn summarize(&self) -> String {
        format!("{} - {}", self.headline, self.location)
    }
}
struct Tweet {
    username: String,
    content: String,
    reply: bool,
    retweet: bool,
}
impl Summary for Tweet {
    fn summarize(&self) -> String {
        format!("{}: {}", self.username, self.content)
    }
}
fn main() {
    let article = NewsArticle {
        headline: String::from("Rust is awesome!"),
        location: String::from("Internet"),
        content: String::from("Rust is a systems programming language..."),
    };
    let tweet = Tweet {
        username: String::from("user123"),
        content: String::from("Hello, world!"),
        reply: false,
        retweet: false,
    };
    println!("Article Summary: {}", article.summarize());
    println!("Tweet Summary: {}", tweet.summarize());
}
```

18.1.1 Polymorphism

A function that accepts any type implementing a trait. Using traits as function parameters:

```
fn notify(item: &impl Summary) {
    println!("Breaking news! {}", item.summarize());
}

fn main() {
    let article = NewsArticle {
        headline: String::from("Rust is awesome!"),
        location: String::from("Internet"),
        content: String::from("Rust is a systems programming language..."),
    };
    let tweet = Tweet {
        username: String::from("user123"),
        content: String::from("Hello, world!"),
```

```
        reply: false,
        retweet: false,
    };
    notify(&article);
    notify(&tweet);
}
```

18.1.2 Trait Bounds and Generics

Using trait bounds in generic functions:

```
fn notify<T: Summary>(item: &T) {
    println!("Breaking news! {}", item.summarize());
}
```

19 Lifetimes

Lifetimes manage how long references are valid to prevent dangling references.

- Ensure references do not outlive the data they point to.
- Specified using apostrophes (e.g., `'a`).
- Prevents references from pointing to invalid data.

```
fn longest<'a>(x: &'a str, y: &'a str) -> &'a str {
    if x.len() > y.len() {
        x
    } else {
        y
    }
}

fn main() {
    let string1 = String::from("long string");
    let string2 = "short";

    let result = longest(string1.as_str(), string2);
    println!("The longest string is {}", result);
}
```

19.1 Lifetime Annotations in Structs

```
struct ImportantExcerpt<'a> {
    part: &'a str,
}

fn main() {
    let novel = String::from("Call me Ishmael. Some years ago...");
    let first_sentence = novel.split('.').next().expect("Could not find a '.'");
    let excerpt = ImportantExcerpt { part: first_sentence };
    println!("Excerpt: {}", excerpt.part);
}
```

19.1.1 Lifetime Elision

Rust applies three rules to infer lifetimes when they are not explicitly annotated:

- Each parameter that is a reference gets its own lifetime parameter.
- If there is exactly one input lifetime parameter, that lifetime is assigned to all output reference parameters.
- If there are multiple input lifetime parameters, but one of them is `&self` or `&mut self`, the lifetime of `self` is assigned to all output reference parameters.

```
fn first_word(s: &str) -> &str {
    let bytes = s.as_bytes();

    for (i, &item) in bytes.iter().enumerate() {
        if item == b' ' {
            return &s[0..i];
        }
    }

    &s[..]
}
```

19.1.2 Static Lifetimes

Static lifetimes are the longest possible lifetimes in Rust. They last for the entire duration of the program. They are stored in the binary's read-only memory.

```
fn main() {

    // A string literal has a 'static lifetime
    let s: &'static str = "I have a static lifetime.";

    // Global variable with 'static lifetime
    static GLOBAL_VAR: &str = "I am a global variable with a static lifetime.";

}
```

20 Smart Pointers

Smart pointers are data structures that not only act like a pointer but also have additional metadata and capabilities.

Single ownership with Box<T>:

```
fn main() {
    let b = Box::new(5);
    println!("b = {}", b);
}
```

Shared ownership with Rc<T>:

```
use std::rc::Rc;

fn main() {
    let a = Rc::new(5);
    let b = Rc::clone(&a);
    println!("a = {}, b = {}", a, b);
}
```
